

Integrating Trichoptera barcodes and big data:

today's systematics

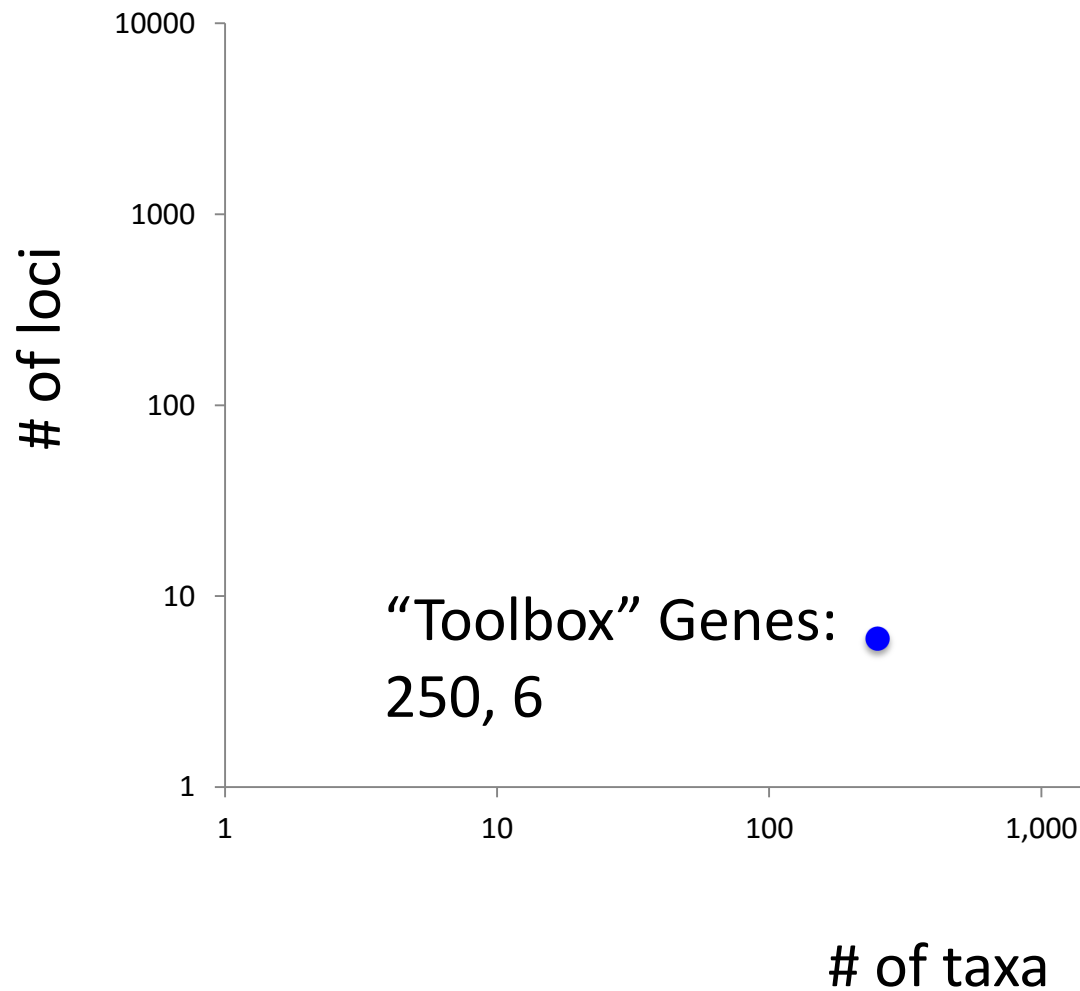

Karl Kjer, UC Davis,
Dept. of Entomology and Nematology

1. Barcodes
2. Transcriptomes
3. Targeted Enrichment

Theme: How do we stitch these very different data into a coherent picture of phylogeny?

The Trichoptera Data

The Trichoptera Data

The Trichoptera Data

The Trichoptera Data

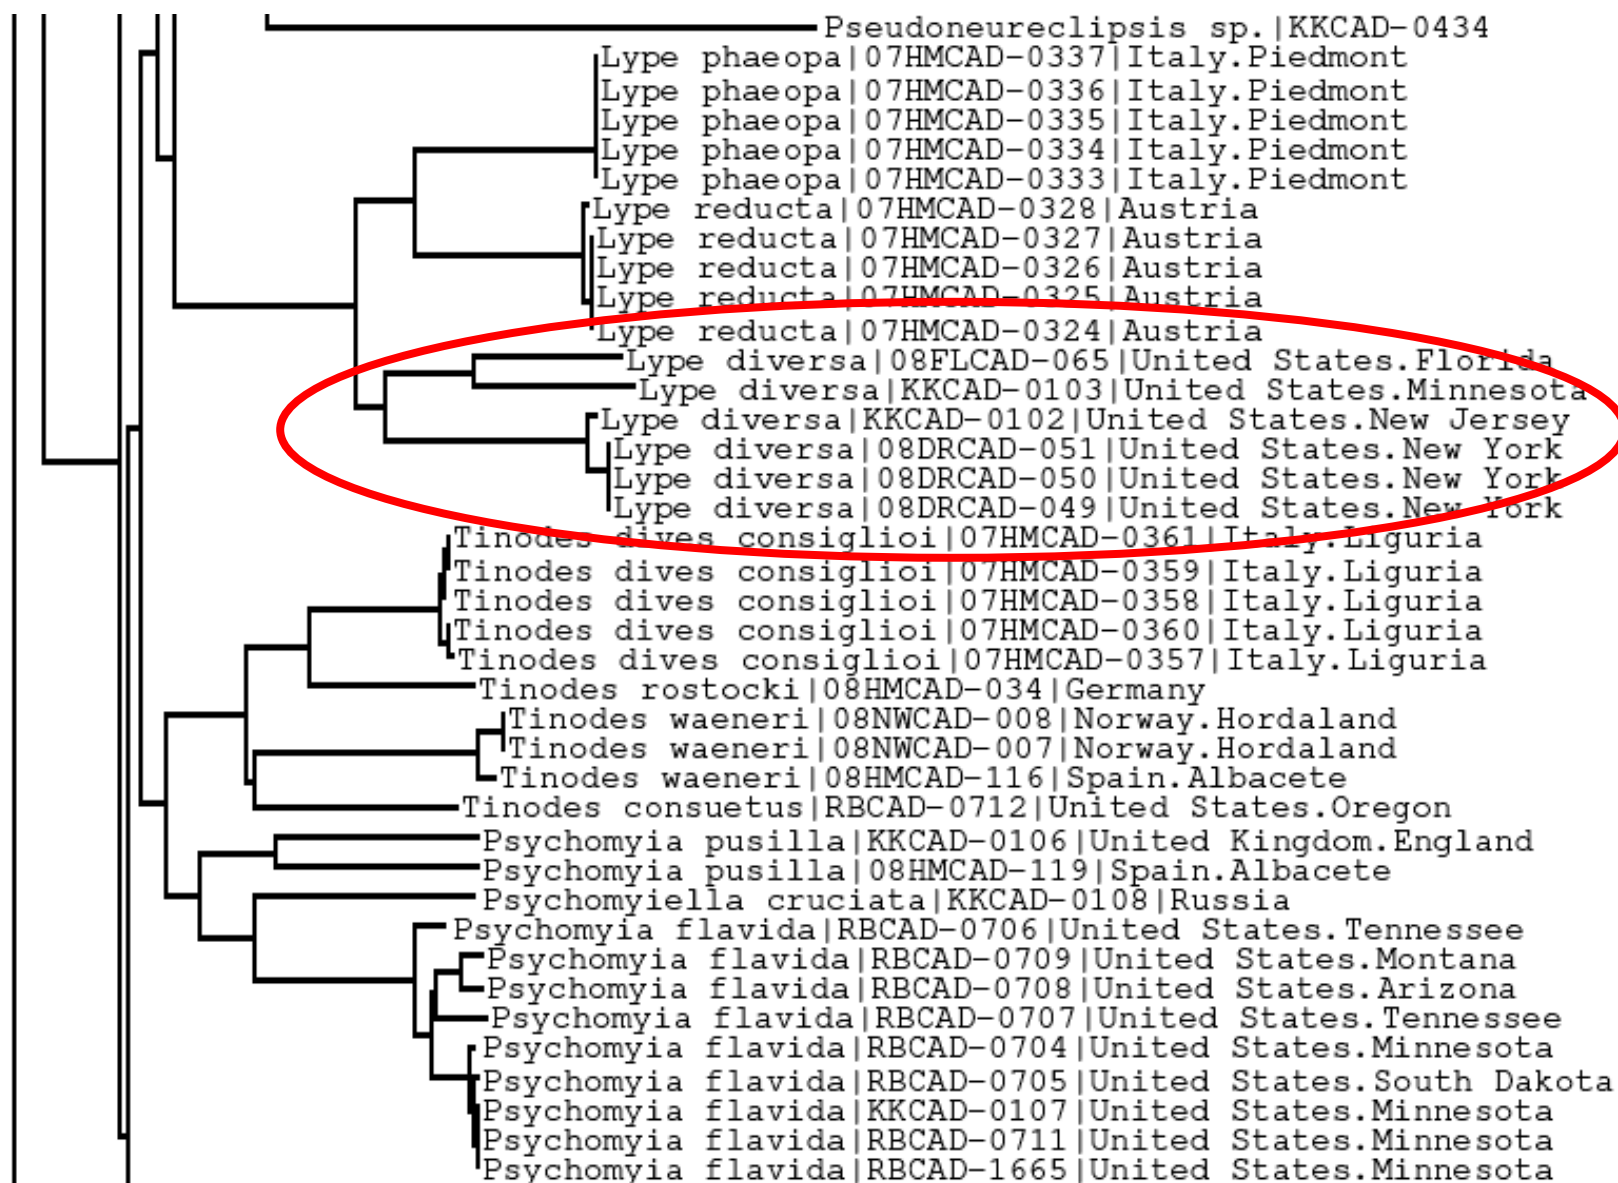

The Trichoptera Data

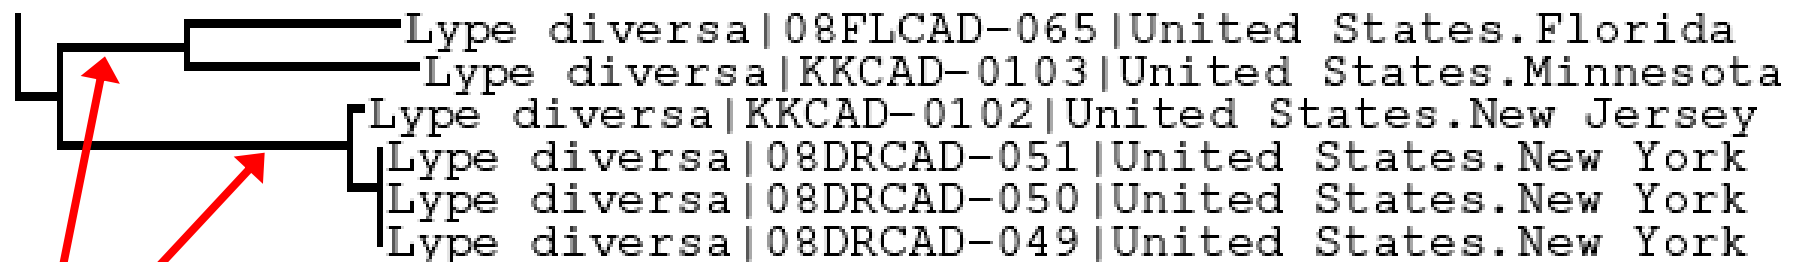

**We have 2000 times this, from over 4,500 Trichoptera species.
And the interesting one is...**

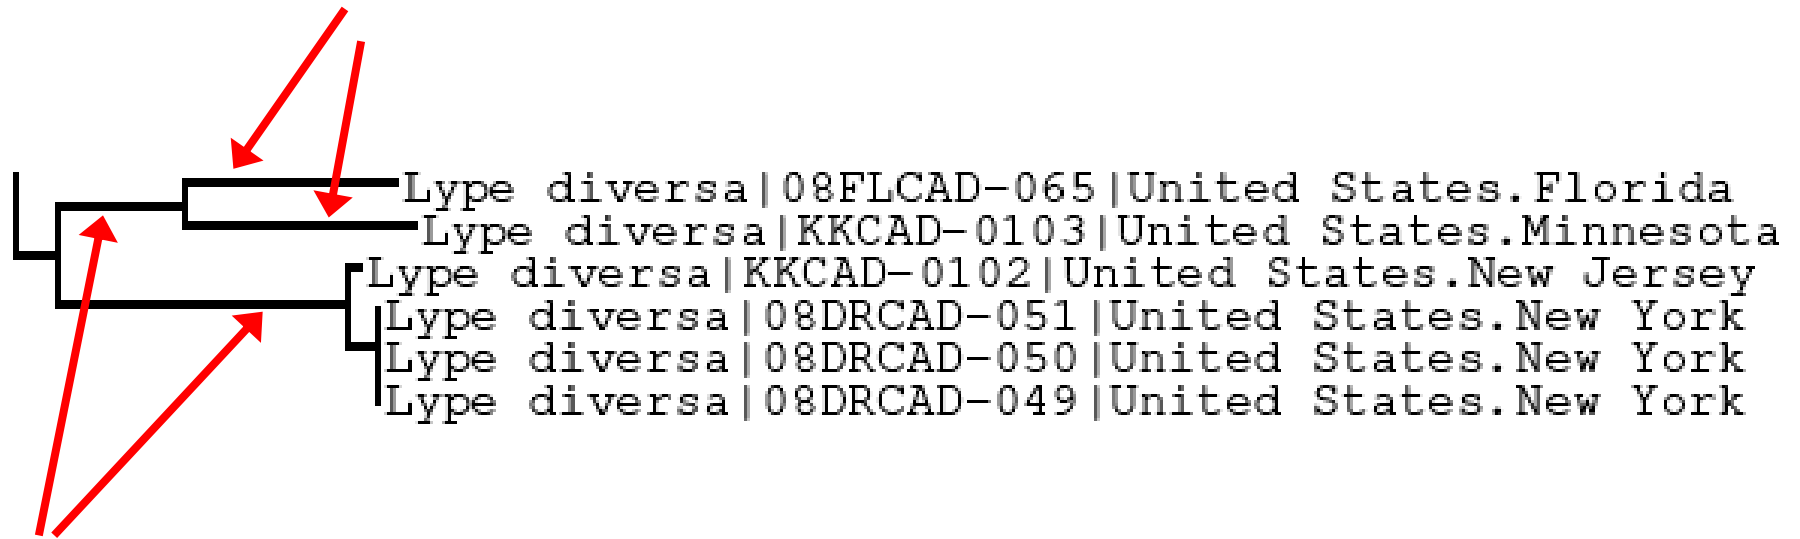

Here. *Lype diversa*

Are these 2 different species?

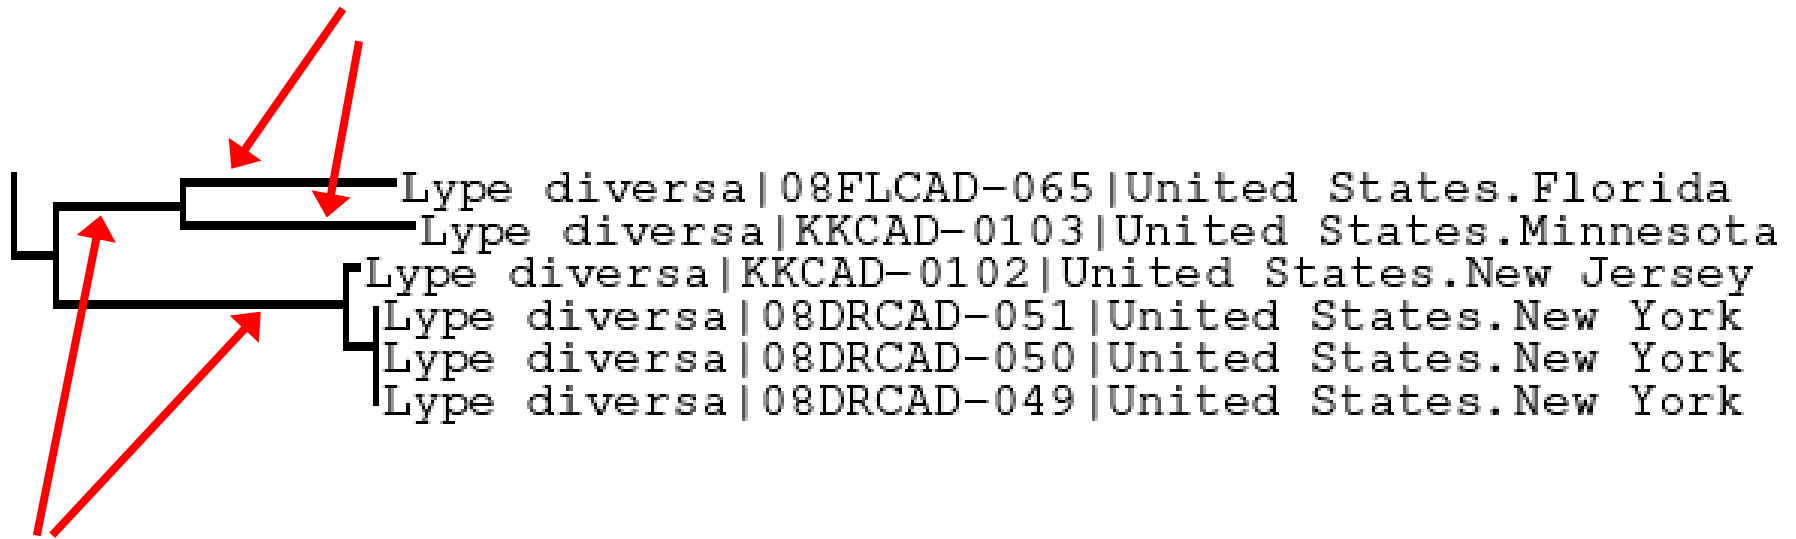

Maybe...what about these?

Are these 2 different species?

We have BINs and MOTUs (which are great, and useful). Are they species?

Maybe...what about these?

Are these 2 different species?

We need more information than barcodes can provide

Lype diversa

Fig. 275. - *Lype diversa*, male genitalia, showing variations of dorsal horn or the tenth tergite. (Ross 1944)

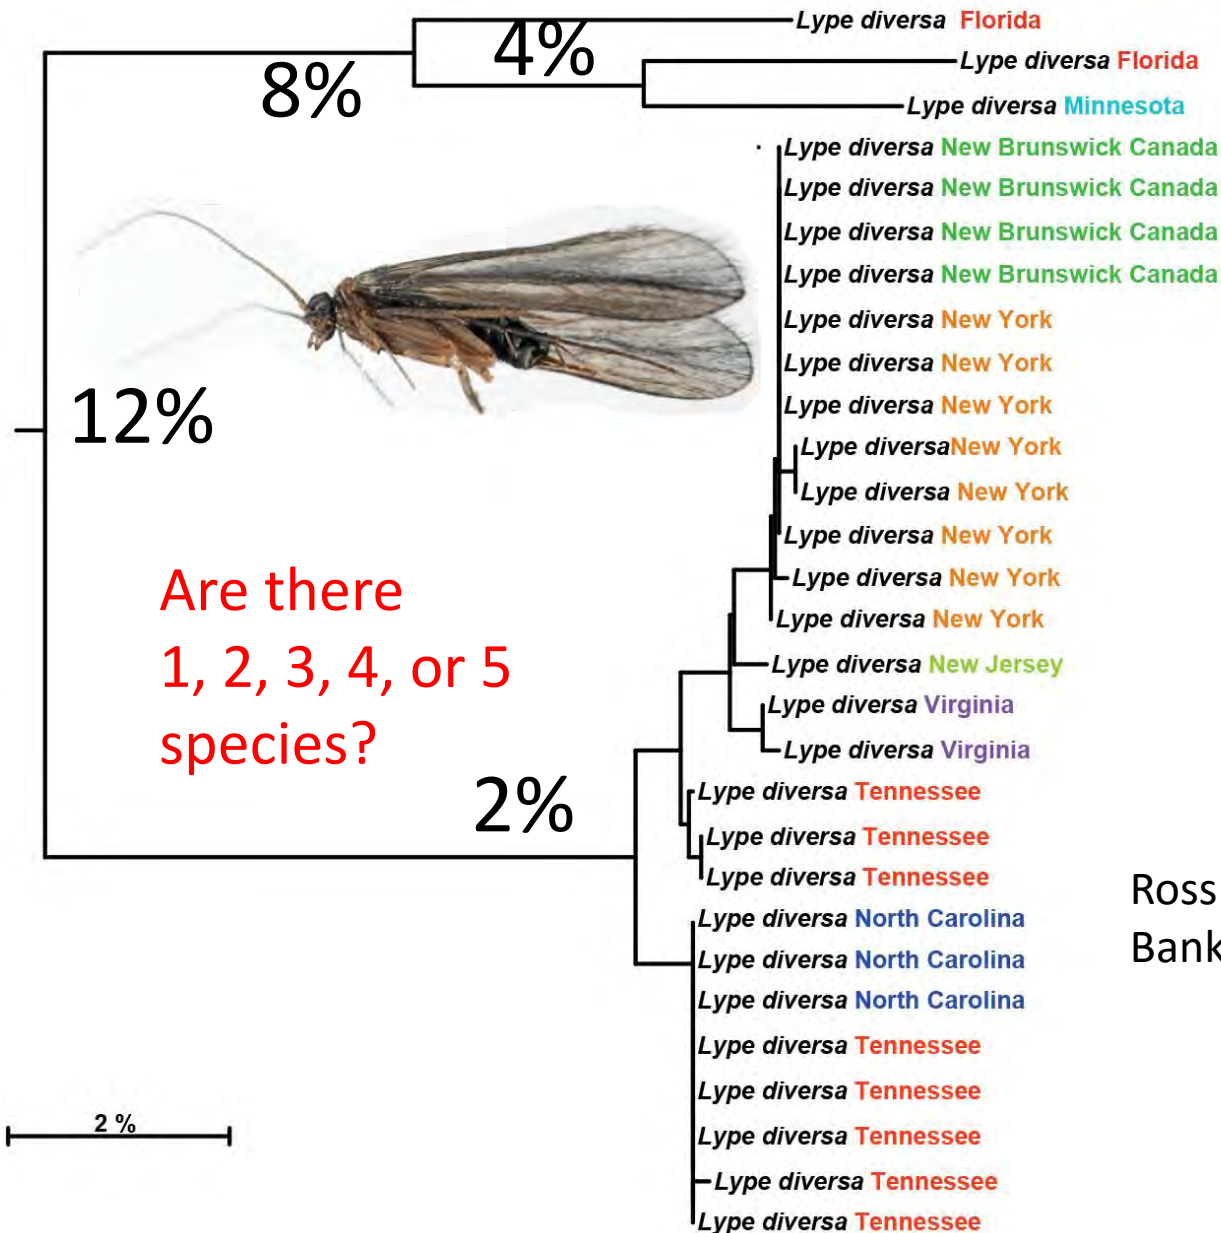

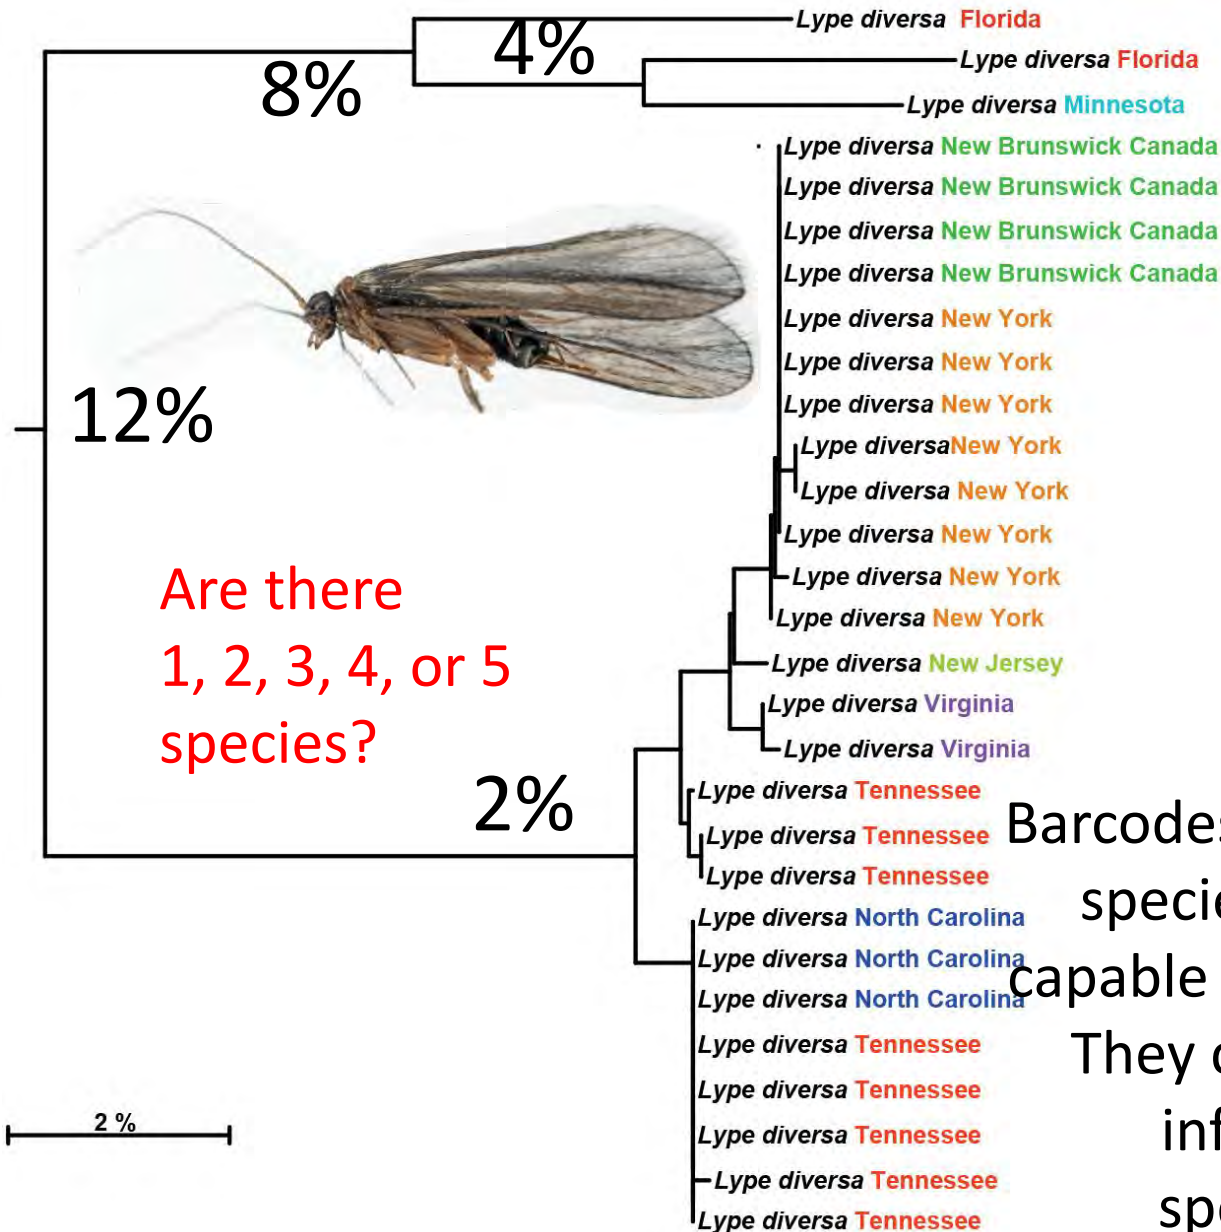

Fig. 275. - *Lype diversa*, male genitalia, showing variations of dorsal horn or the tenth tergite. (Ross 1944)

Ross noticed this back in '44
Banks must have noticed it in '14

Are there
1, 2, 3, 4, or 5
species?

Fig. 275. - *Lype diversa*, male genitalia, showing variations of dorsal horn or the tenth tergite. (Ross 1944)

Barcodes alone may not **define** species, but are perfectly capable of describing diversity. They can be a reciprocally informative part of species description

This illustrates both the power, and the challenge of barcodes.

Fig. 275. - *Lype diversa*, male genitalia, showing variations of dorsal horn or the tenth tergite. (Ross 1944)

Genetic clusters that correspond to fixed morphological differences, combined with geography = **New species**

We see this all the time

World Diplectrona COI NJ tree

- *Diplectrona modesta* complex
- COI haplotype clusters

Harvey, Geraci, Robinson,
Morse, Kjer, Zhou, 2012
Terr. Arth. Rev.

Challenge:

It is hard to distinguish between
inter-species and intra-species variation

Opportunity:

If we can associate distinct BINs with fixed morphological characters, we can increase confidence in species delineation and accelerate formal species description.

The database

The screenshot shows the Trichoptera Barcode of Life website. The browser address bar displays "trichopterabol.org". The website header includes navigation links (Home, About Us, Contact Us), a date (1/7/2012), a text size selector, and a search bar. The main banner features the iBOL logo, the text "Freshwater Biosurveillance Trichoptera barcode of life", and illustrations of a caddisfly and its larva. A "progress" sidebar on the left lists: specimens barcoded: 18549, species barcoded: 2636, and unnamed barcode clusters found: 781. Below this is a "science" sidebar with links to Vision, Species Checklists, Collection Protocols, Submit Data (BOLDSYSTEMS), Lab Procedures, and FAQs. The main content area has a "Welcome" section with a detailed paragraph about the project's goals and a "Trichoptera World Checklist" link. To the right of the welcome text are links for "OTHER WG 1.7 CAMPAIGNS": EPHEMEROPTERA (Mayflies), ODONATA (Dragonflies & Damselflies), and PLECOPTERA (Stoneflies). Further right is an "iBOL Overview" box with text about the project's timeline and goals. At the bottom right is a "photos" section showing a close-up of caddisfly larvae. A "community" sidebar is partially visible at the bottom left.

Welcome

Welcome to the Trichoptera Barcode of Life campaign website. Launched in mid-2007, this DNA barcoding campaign aims to build a comprehensive COI barcode reference library for all caddisfly (Insecta: Trichoptera) species in the world (ca. 13, 000 species). Fulfilling such an ambitious goal is not an easy task. This project is expected to be a long-term research program. We are fully aware of the challenges, but also anticipate exciting discoveries during the progress of the campaign. Instead of trying to explore multiple gene markers across a variety of taxa, the Trichoptera Barcode of Life campaign focuses on a standardized mitochondrial COI gene fragment for this group of organisms. **Through this approach, species diagnosis for any caddisfly in the world using DNA sequences will soon become a reality.** Meanwhile, we incorporate the most up-to-date **Trichoptera World Checklist** as the master checklist to ensure that the recent taxonomy is employed by the campaign.

Support from Trichoptera workers is critical to this barcoding effort. To ease the communications between all participating members, we built this website with a hope to provide these services:

- Provide instructions and protocols for DNA barcoding of

OTHER WG 1.7 CAMPAIGNS:

EPHEMEROPTERA
Mayflies

ODONATA
Dragonflies & Damselflies

PLECOPTERA
Stoneflies

iBOL Overview

iBOL - The International Barcode of Life Project. This project will oversee the assembly of DNA barcodes for 5M sequences & 500K species by 2014. The freshwater bio-surveillance working group (WG 1.7) will gather DNA barcode records for four groups of invertebrates that are critical to water quality monitoring programs around the world.

photos

Here is how it all started

*Xin and I talk about
China in 2002*

R

We conclude that **China is stepping up**
on the world stage, and will have resources
What do they want? **Big science.**
What impresses them? **Big names, Science papers**

***Xin and I talk about
China***

R

***We saw that the barcode
initiative was big science, and
Paul Hebert is a name China
would know: Postdoc there.***

Taxon Description (Wikipedia)

The **caddisflies** are an order, **Trichoptera**, of insects with approximately 12,000 described species. Also called **sedg**-flies or **rail**-flies, they are small moth-like insects having two pairs of hairy membranous wings. They are closely related to Lepidoptera (moths and butterflies) which have scales on their wings, and the two orders together form the superorder Amphiesmenoptera. Caddisflies have aquatic larvae and are found in a wide variety of habitats such as streams, rivers, lakes, ponds, spring seeps, and temporary waters (vernal pools). The larvae of many species make protective cases of silk decorated with gravel, sand, twigs or other debris. The name "Trichoptera" comes from Greek: (, "hair") + (, "wing"). RESEARCH ARTICLE

Open Access

DNA barcoding facilitates associations and diagnoses for Trichoptera larvae of the Churchill (Manitoba, Canada) area

David E Ruiter¹, Elizabeth E Boyle² and Xin Zhou^{3*}

- 3,310 COI barcodes (adults + larvae)
- 2/3 larval caddisflies from Churchill now identifiable

Useful for Identification:

Many applications for larval associations

Ruiter, Boyle, Zhou*. 2013. *BMC Ecology*

The database is **useful for phylogeny**: Add another gene for a species-level phylogeny

Kjer et al., 2014

COI is **ideal** for barcoding because a large enough fragment is not expected to be identical across species

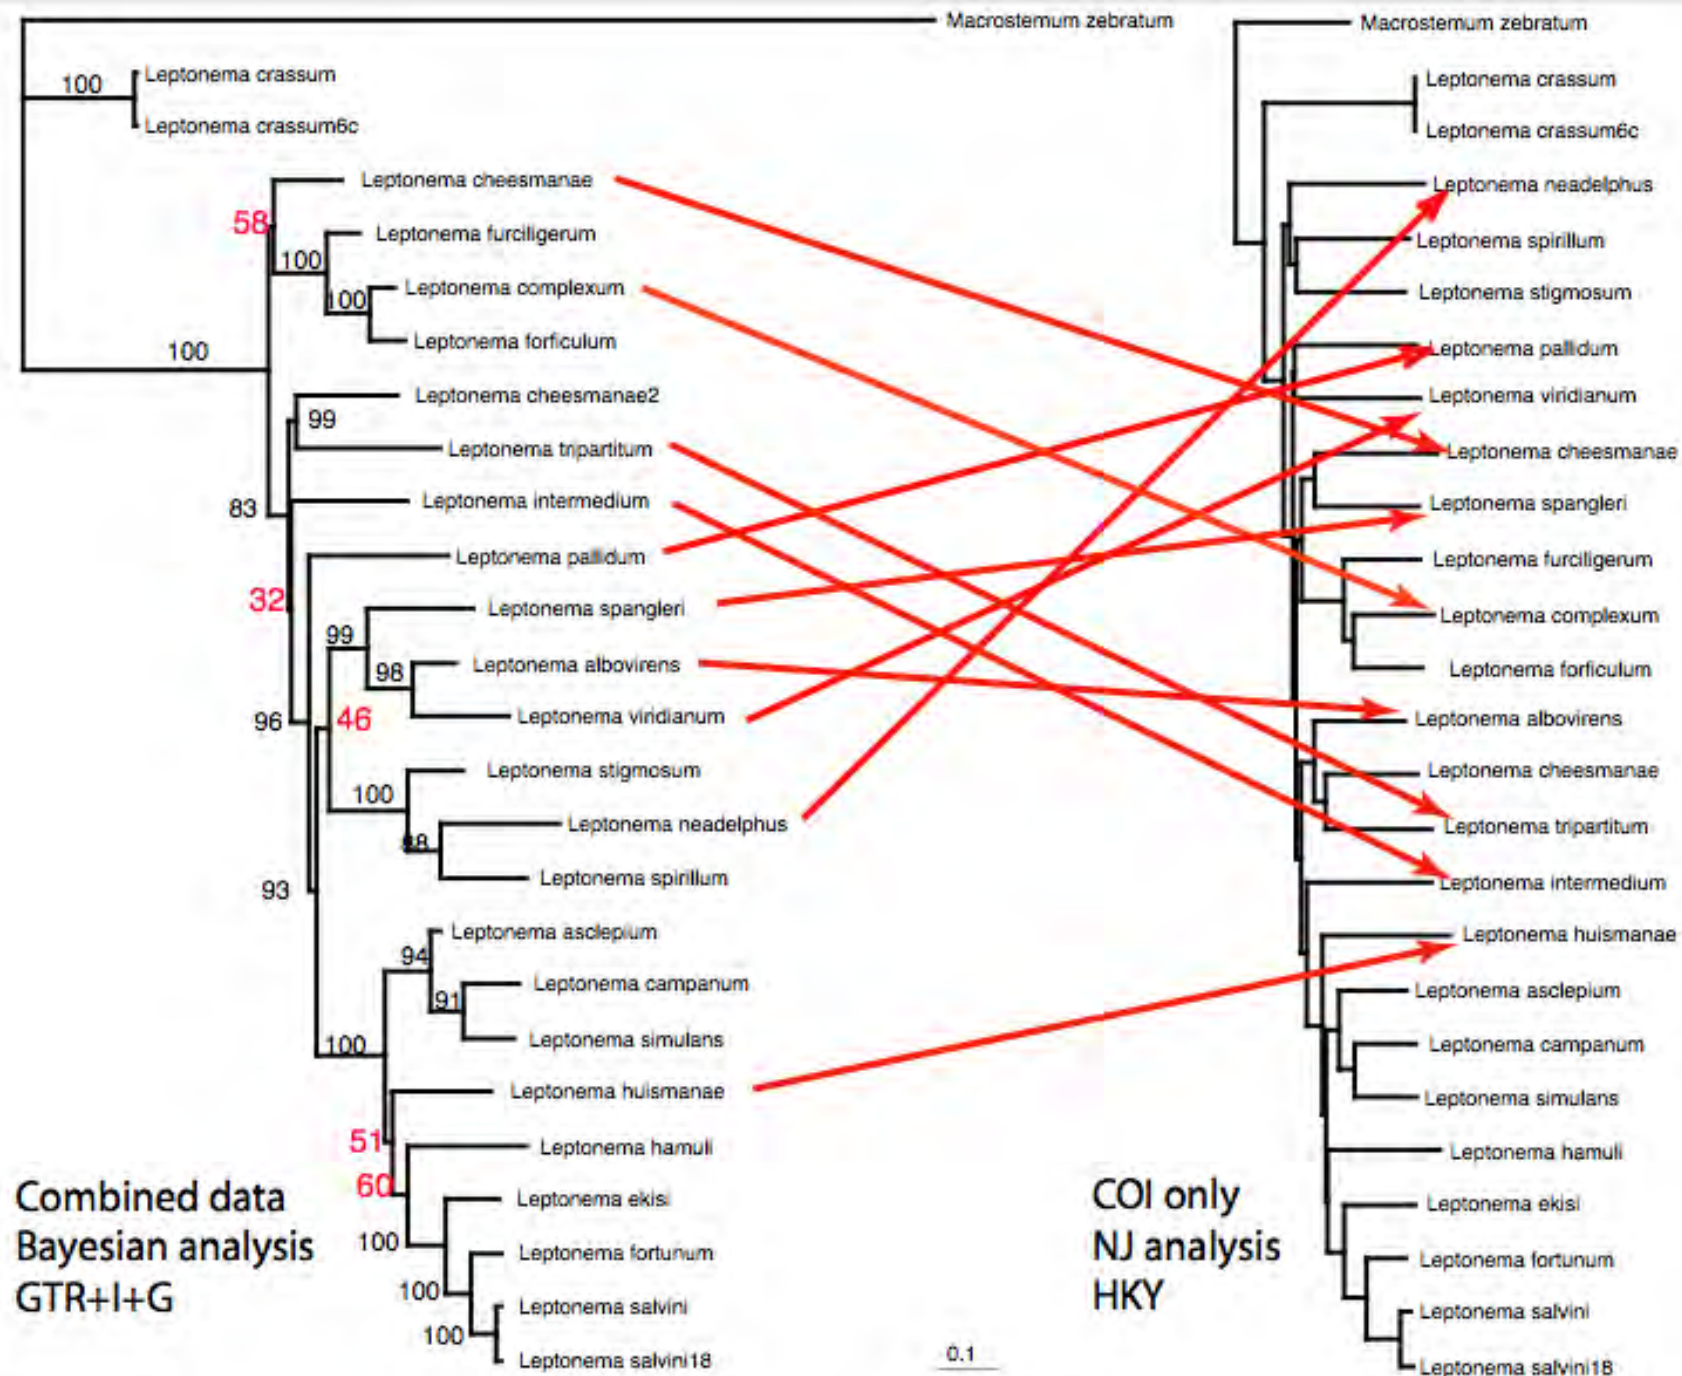

But fast evolving genes are problematic for phylogenetics

A phylogram with long terminal branches, and short internodes is the classic “hard” problem in phylogenetics.

COI, by itself, especially when analyzed with NJ is at best, an interesting hypothesis.

The Trichoptera tree of life

45,000 barcodes from all families

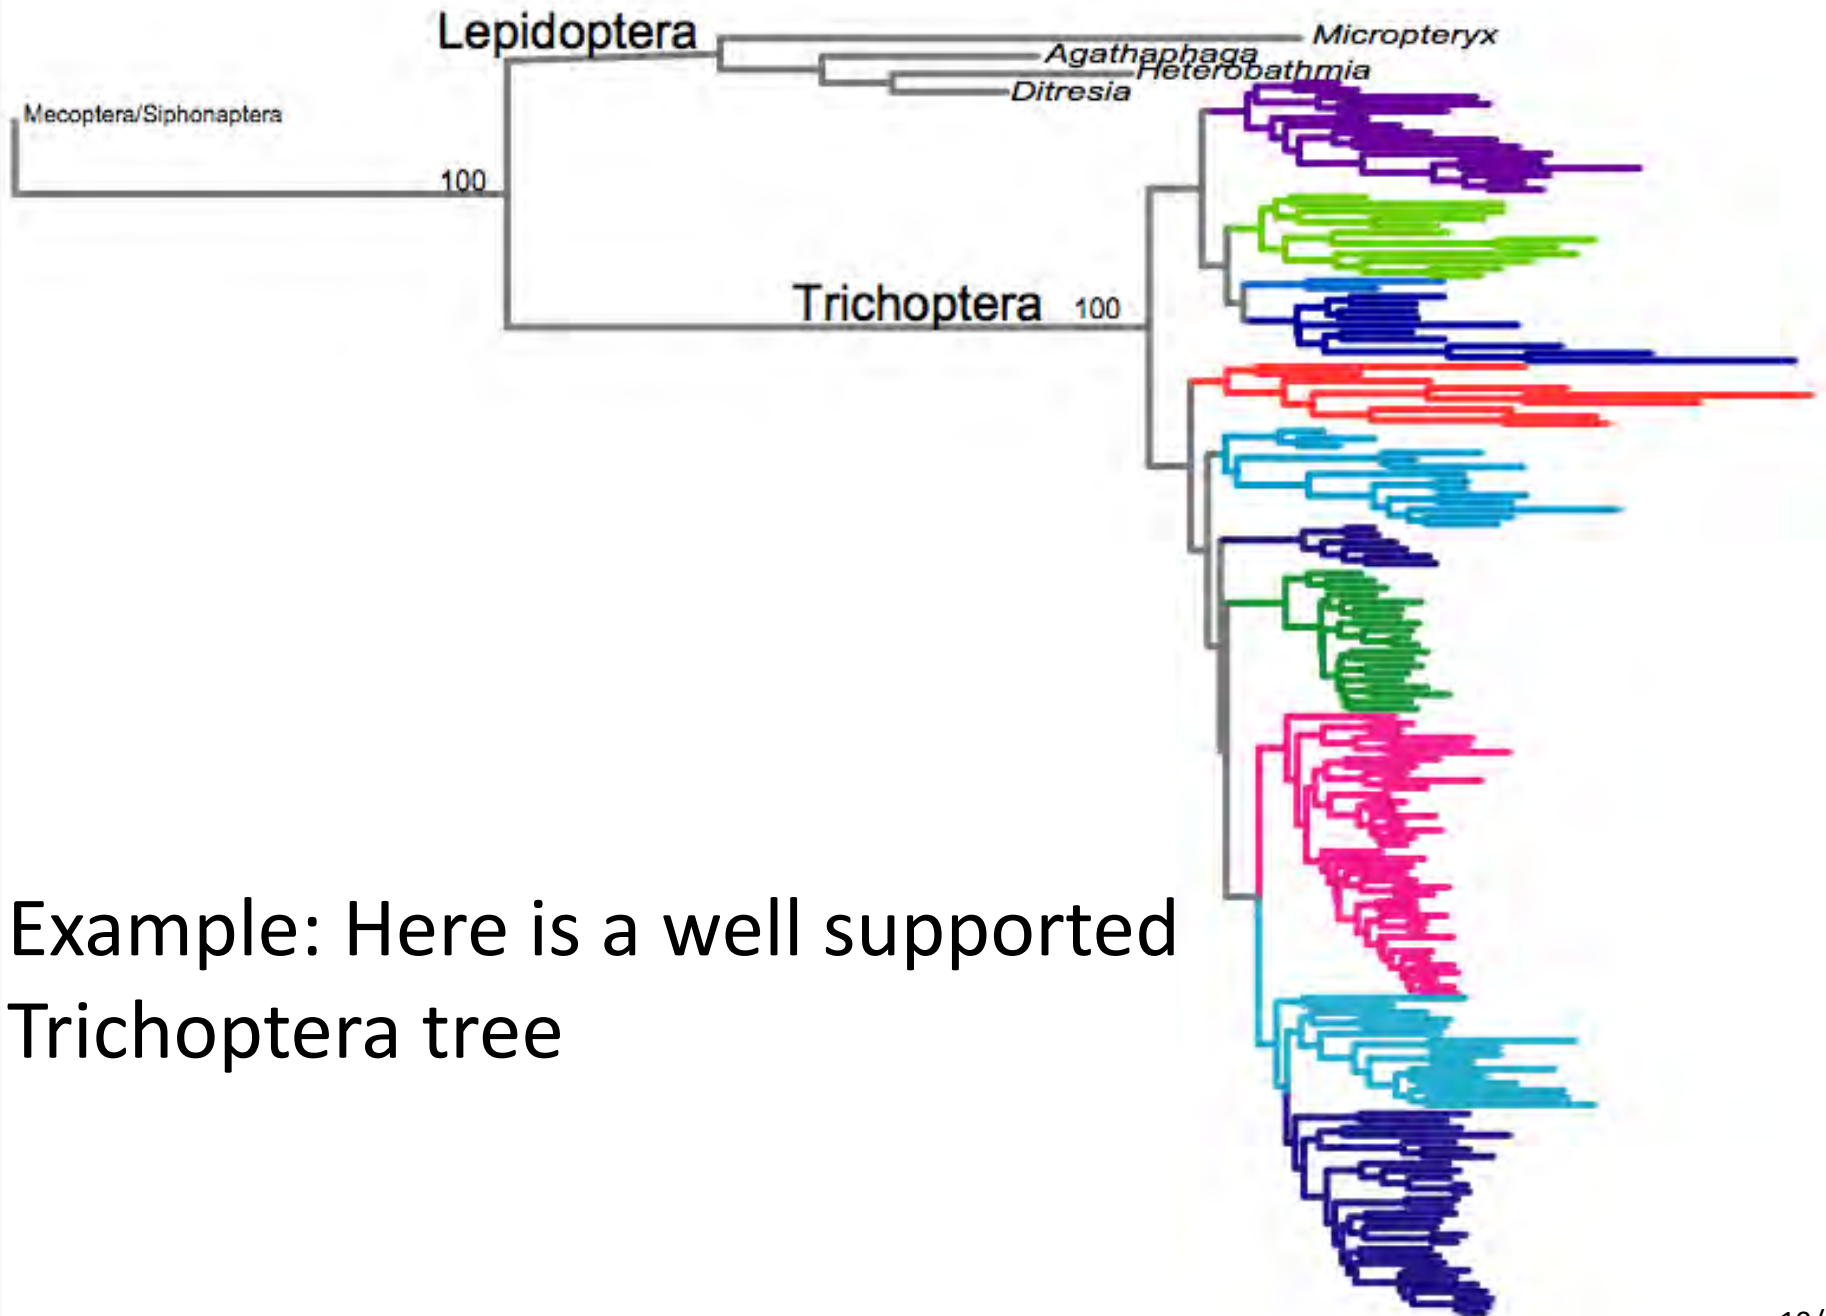

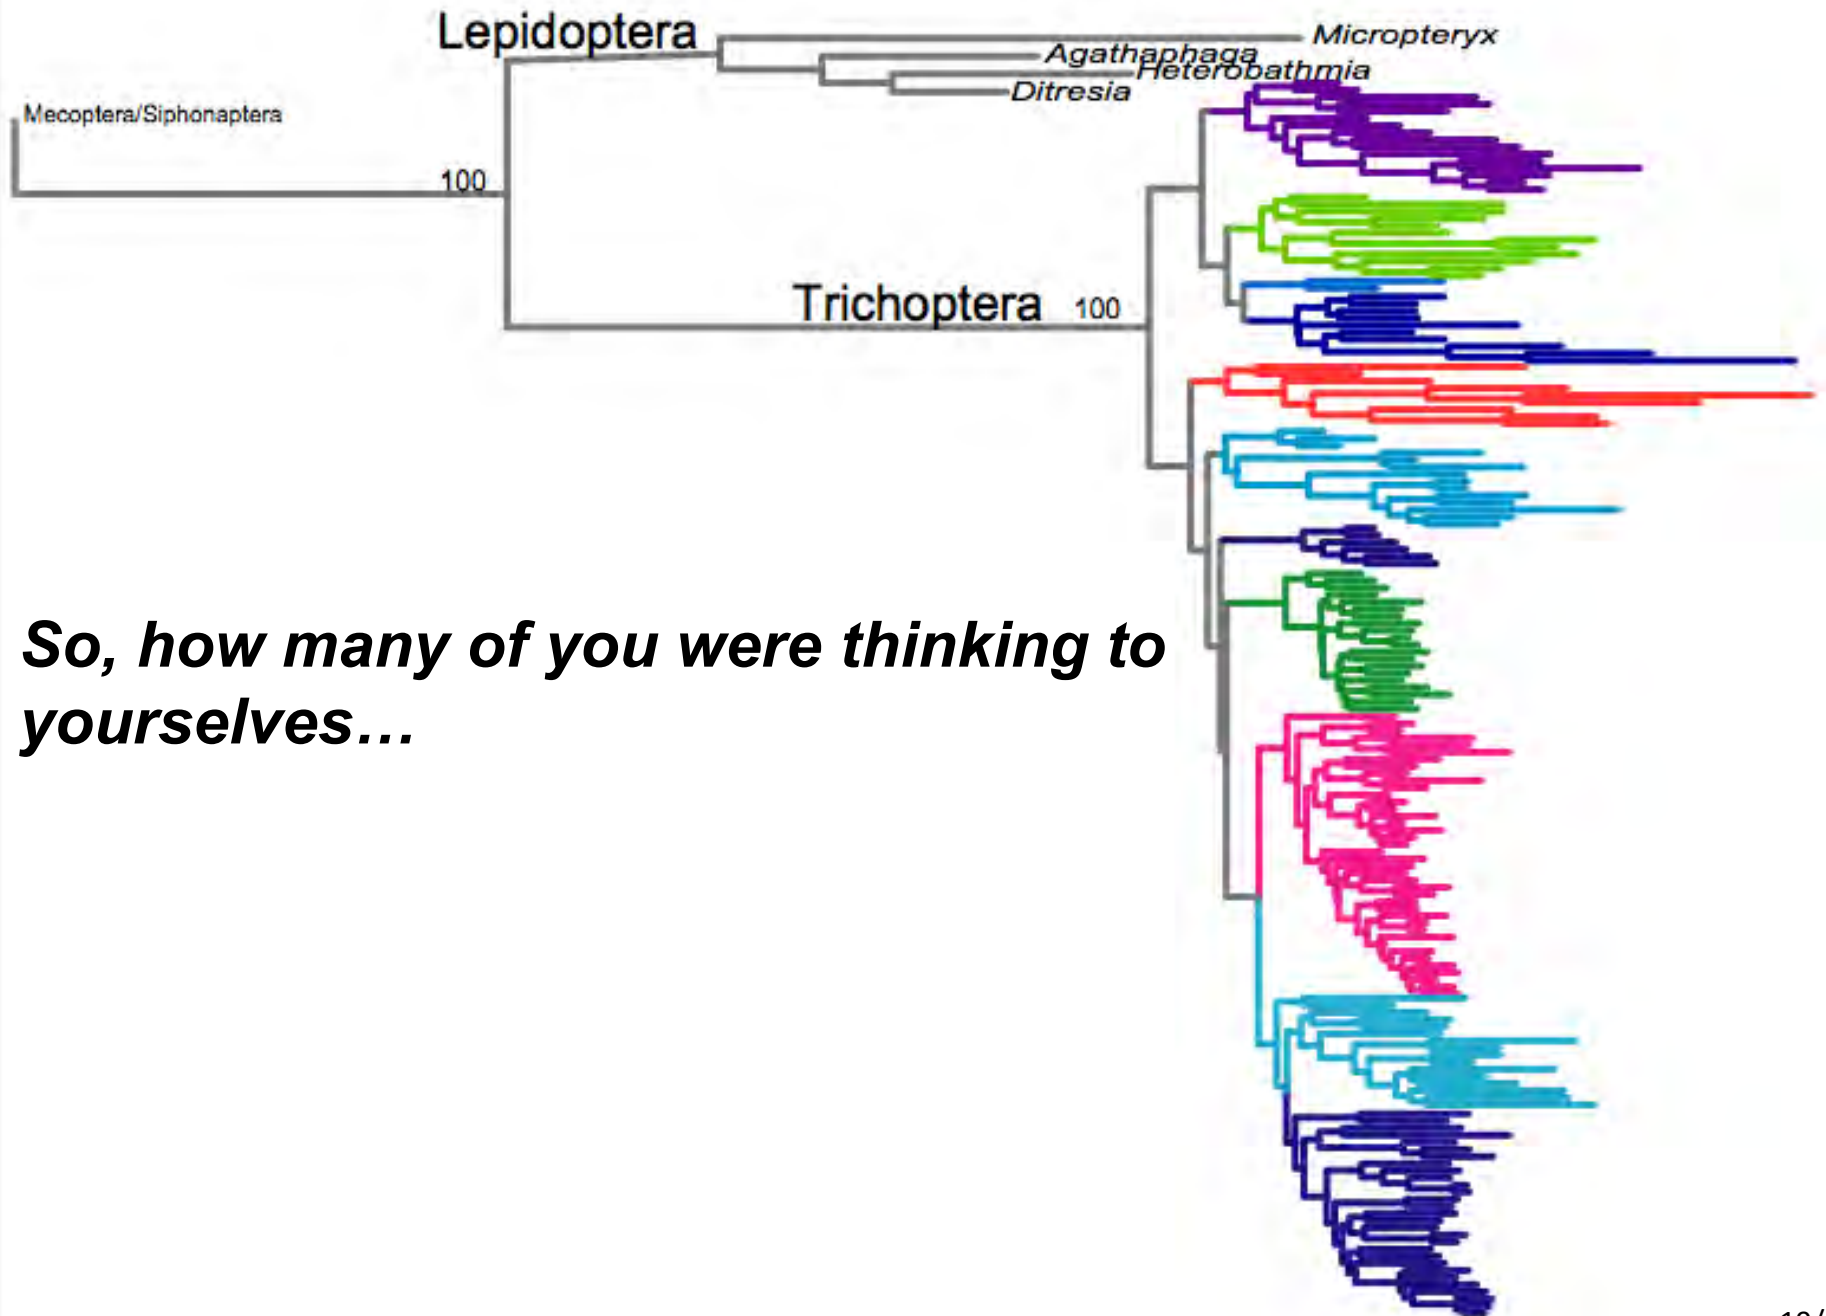

We want to complete the Trichoptera “tree of life”

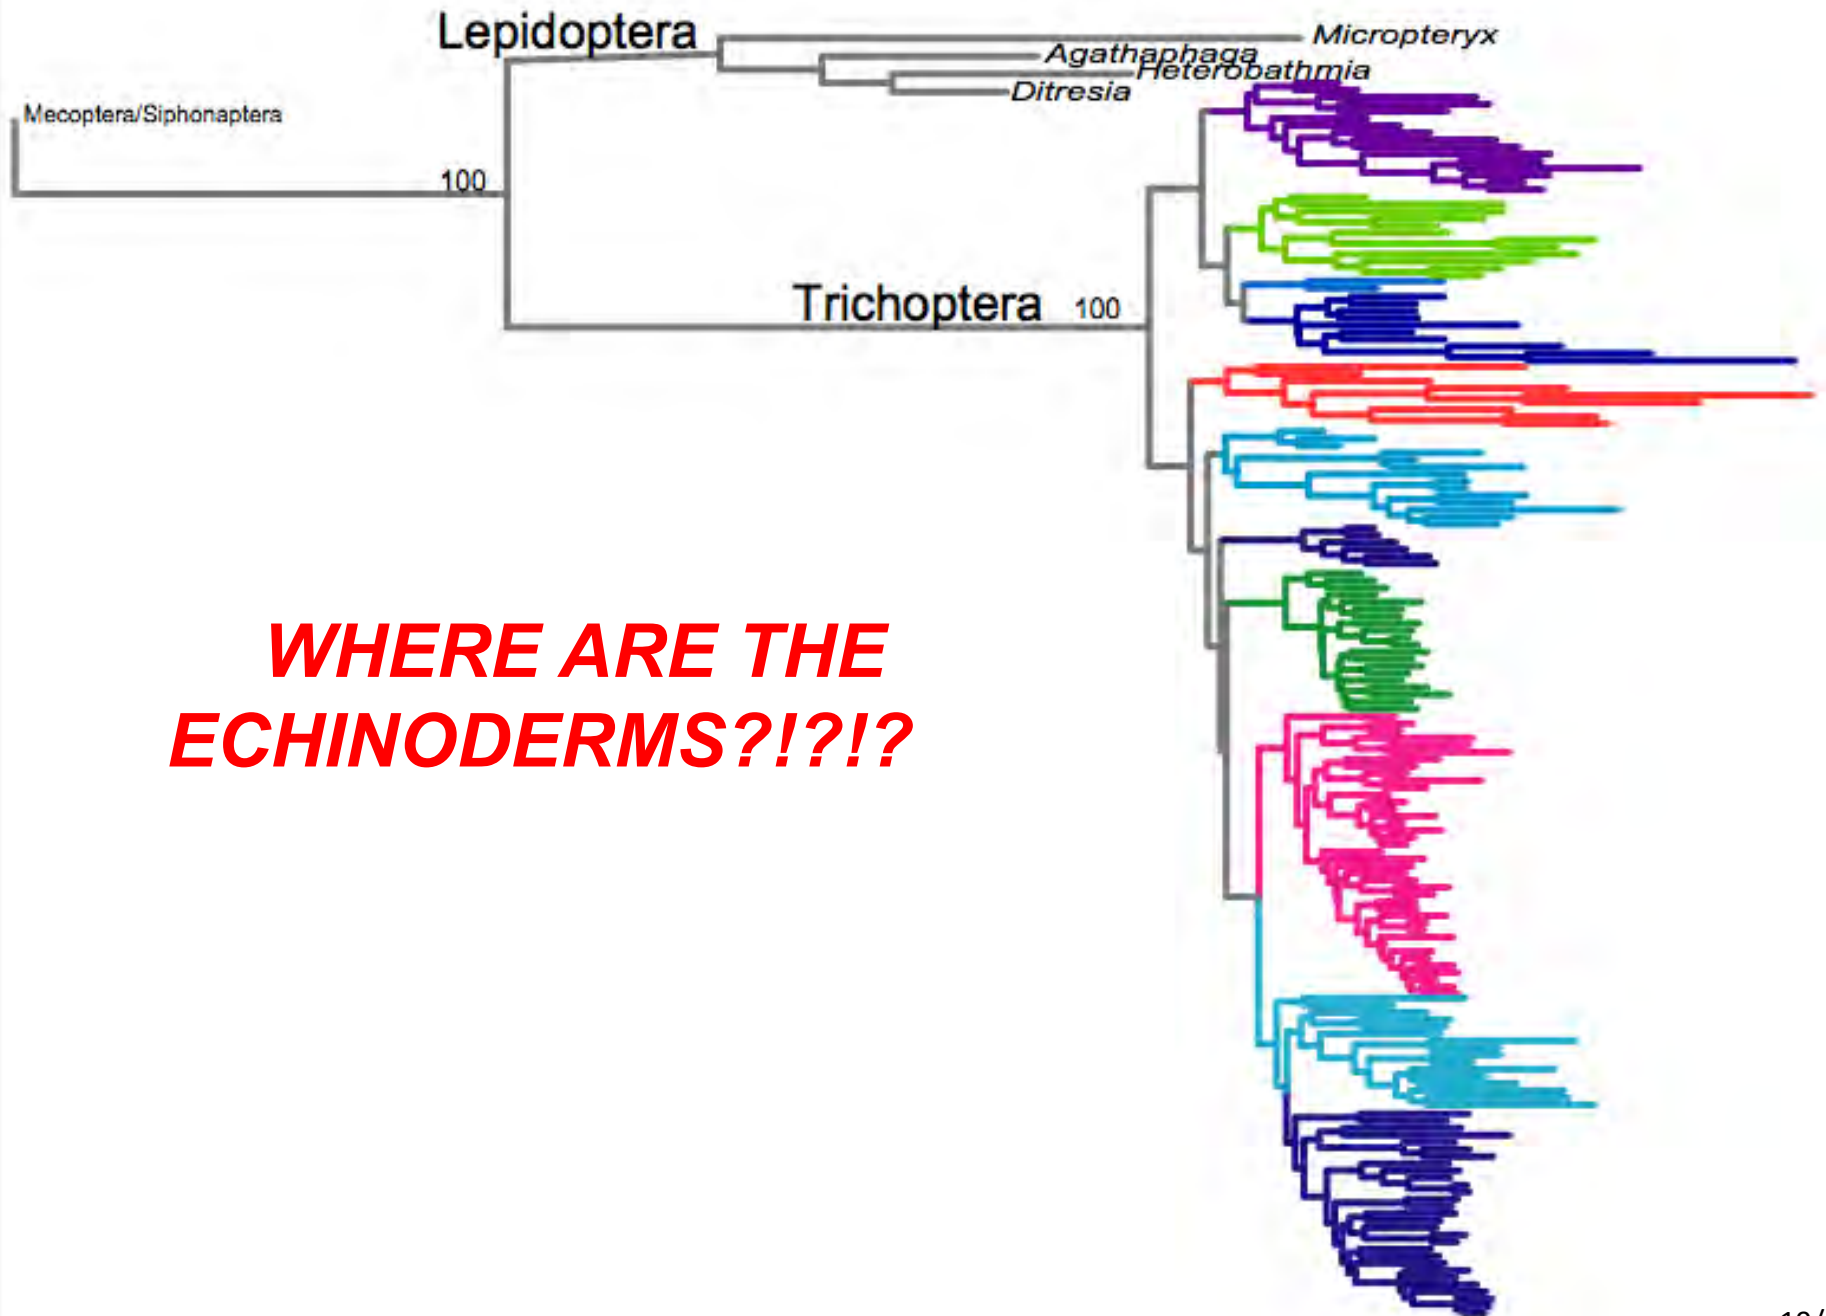

Strategy:
Fix nodes with other data, and then fill out the terminal taxa with COI

Can we do this?

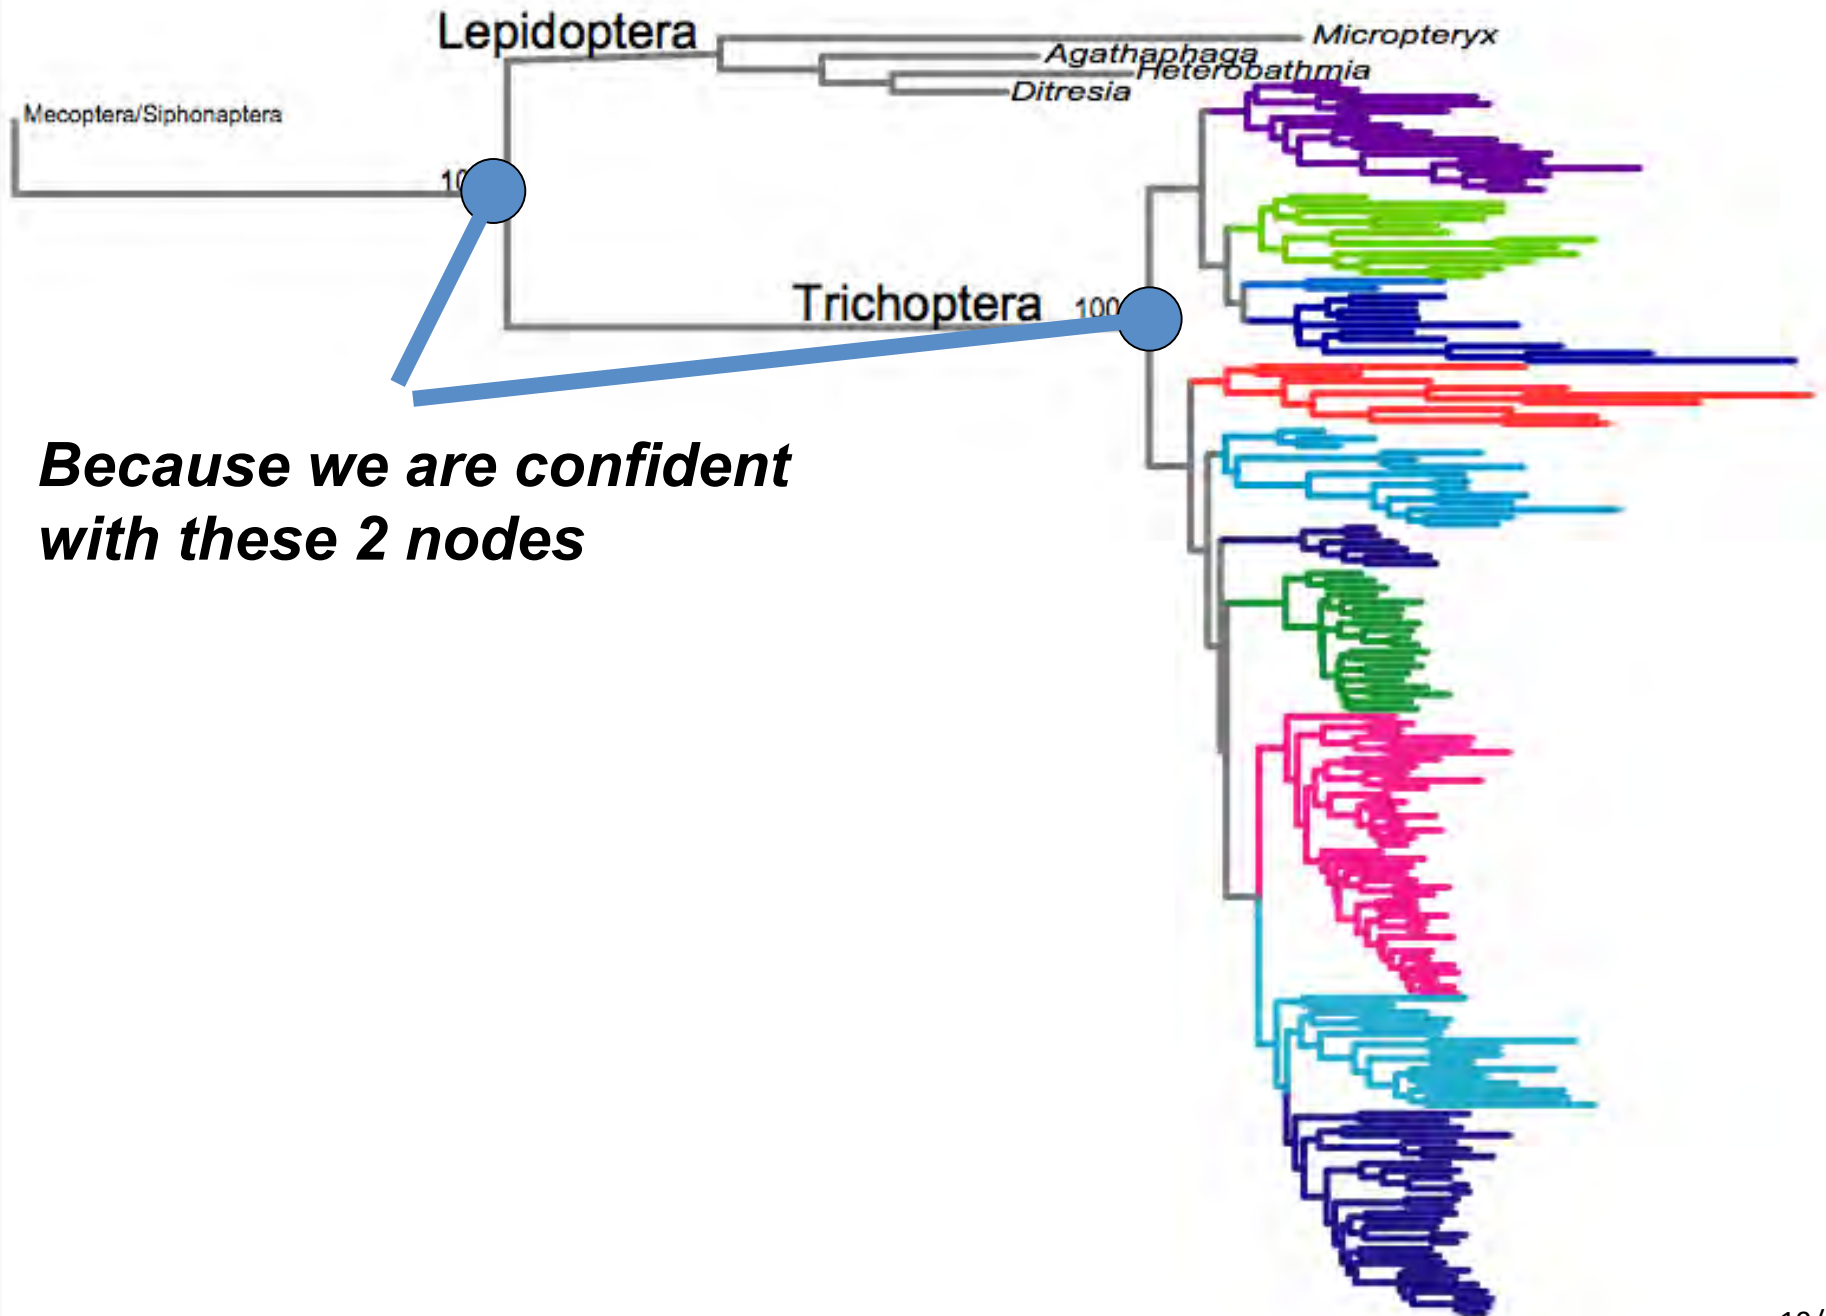

So, how many of you were thinking to yourselves...

Using the same logic, we can estimate a phylogeny of *Macronematinae*, rooted with *Arctopsychinae*...all in *Hydropsychidae*

Here is a tree with 1,000 macronematines, and arctopsychines, one rooting the other

This could work

Annulipalpia

Look at yellow dots

Annulipalpia

Trees with barcodes

Trees with barcodes

Trees with barcodes

Genus *Chimarra*:

The “little black ones”

Largest in Trichoptera with ~750 species

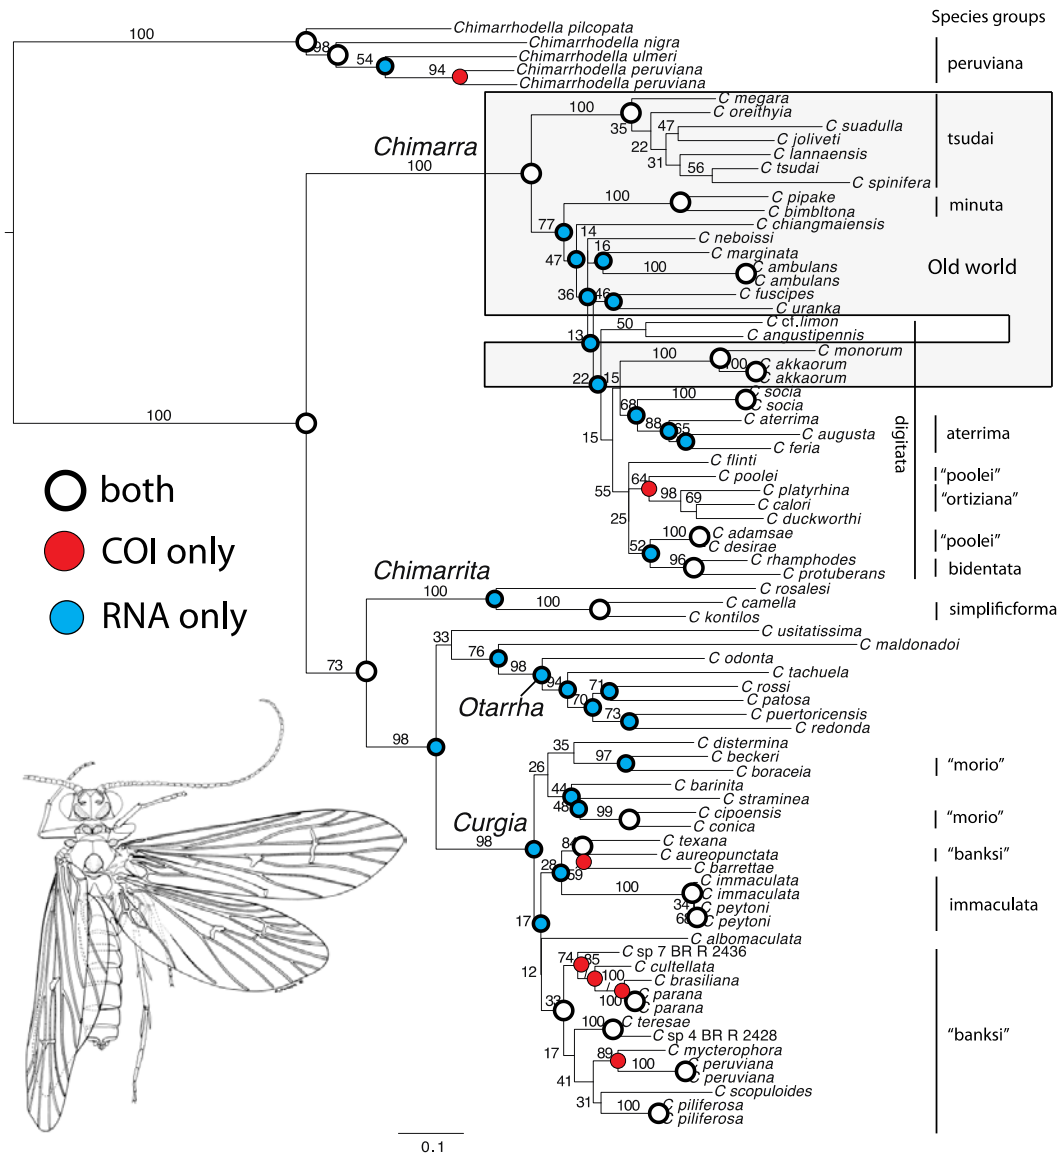

BugGuide.net Photo by Ken

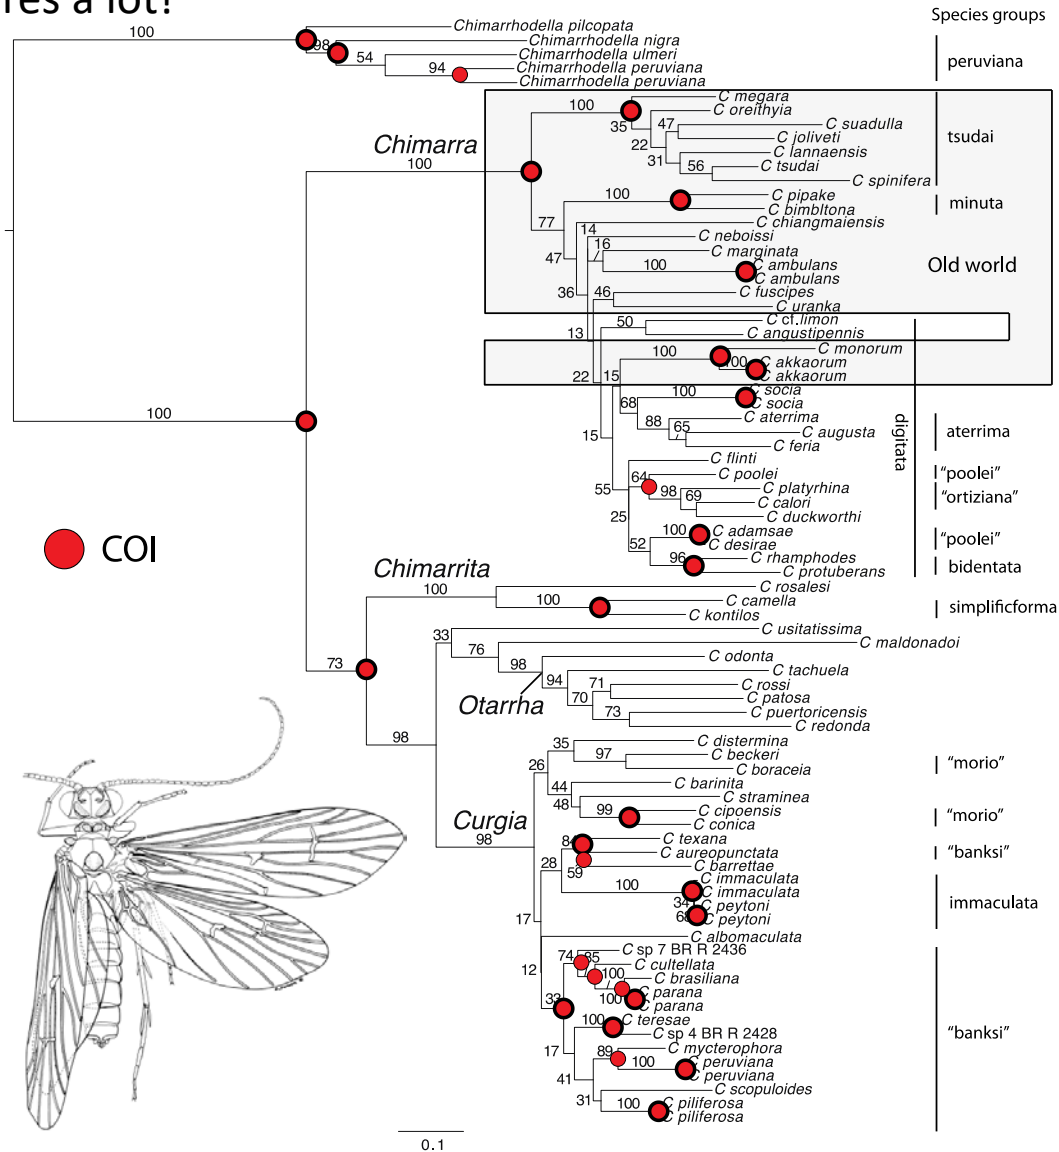

Which one will dominate a combined analysis?

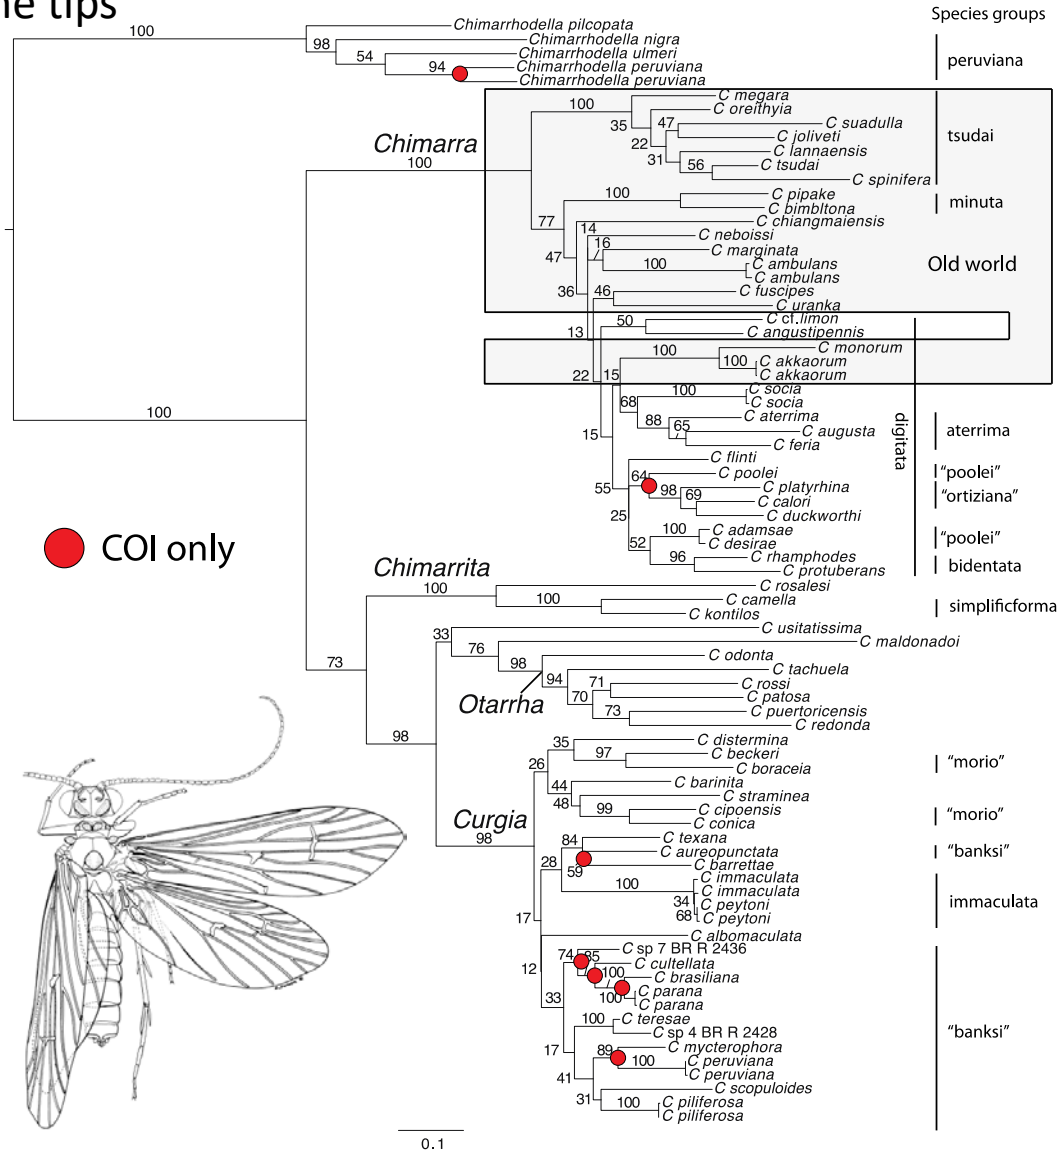

Combined: Judged by morphology, this is a great tree!

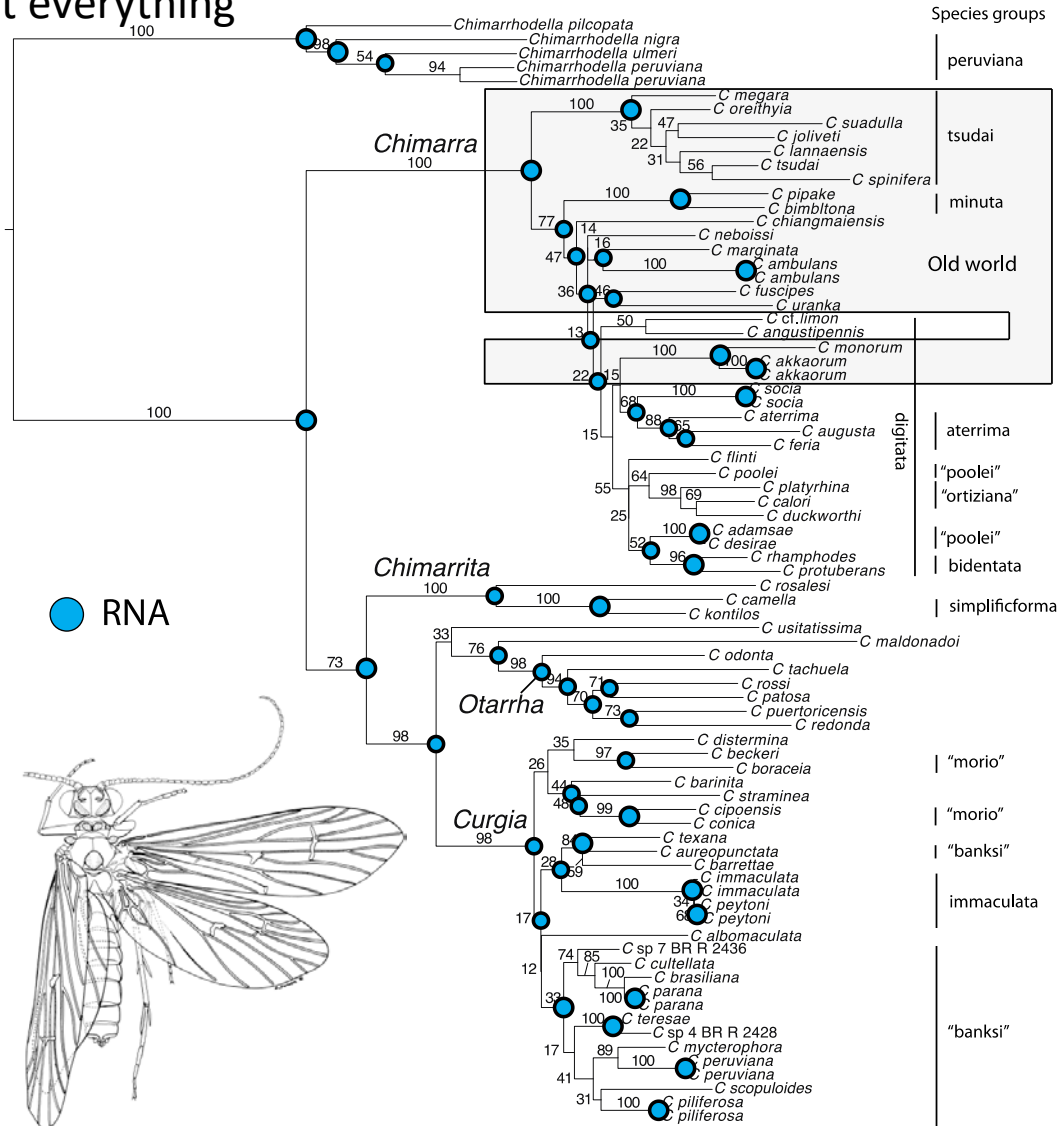

Barcode captures a lot!

But favors the tips

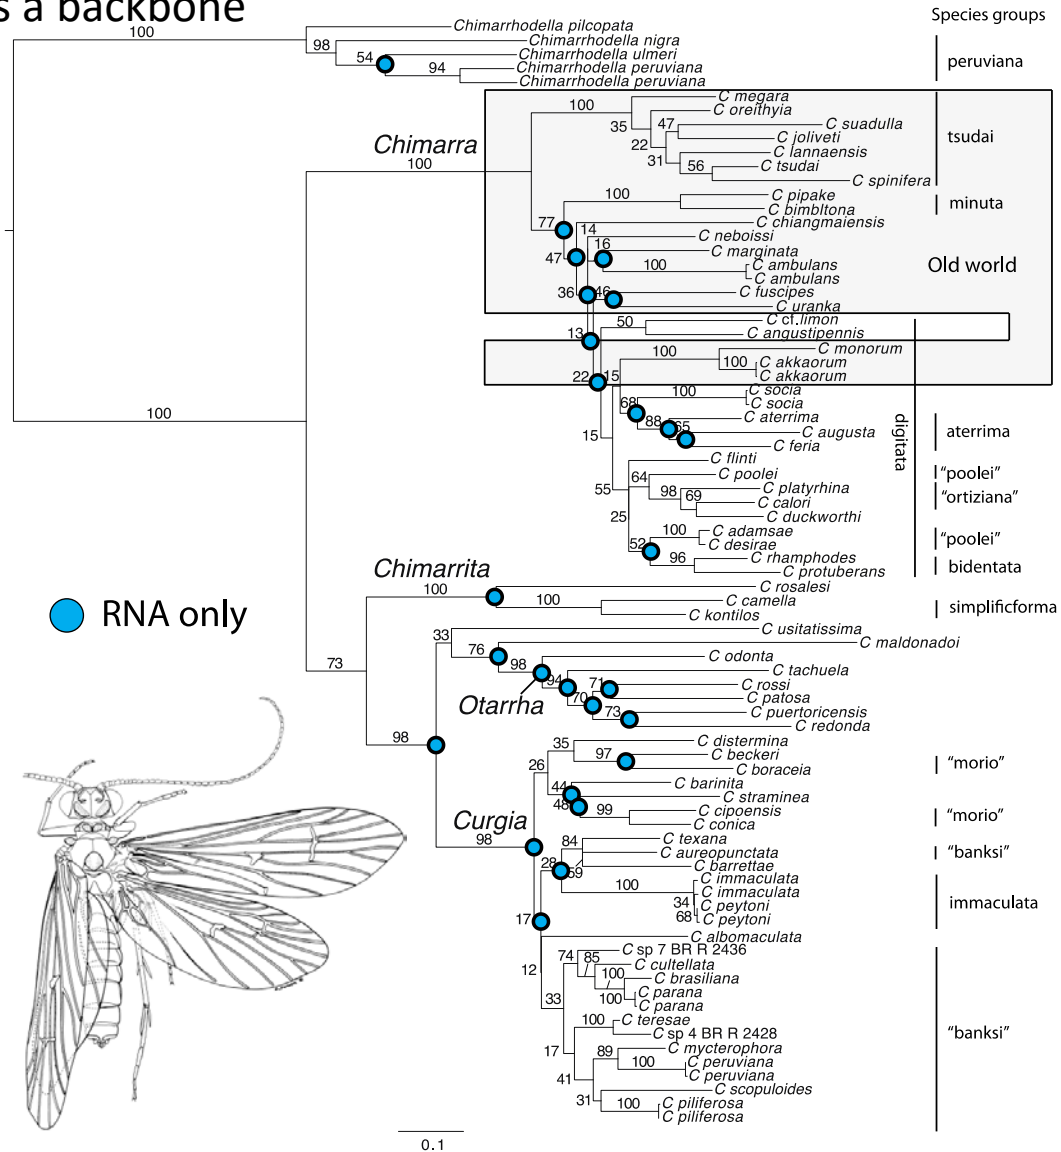

RNA gets almost everything

0.1

...and provides a backbone

How about *Rhyacophila*?

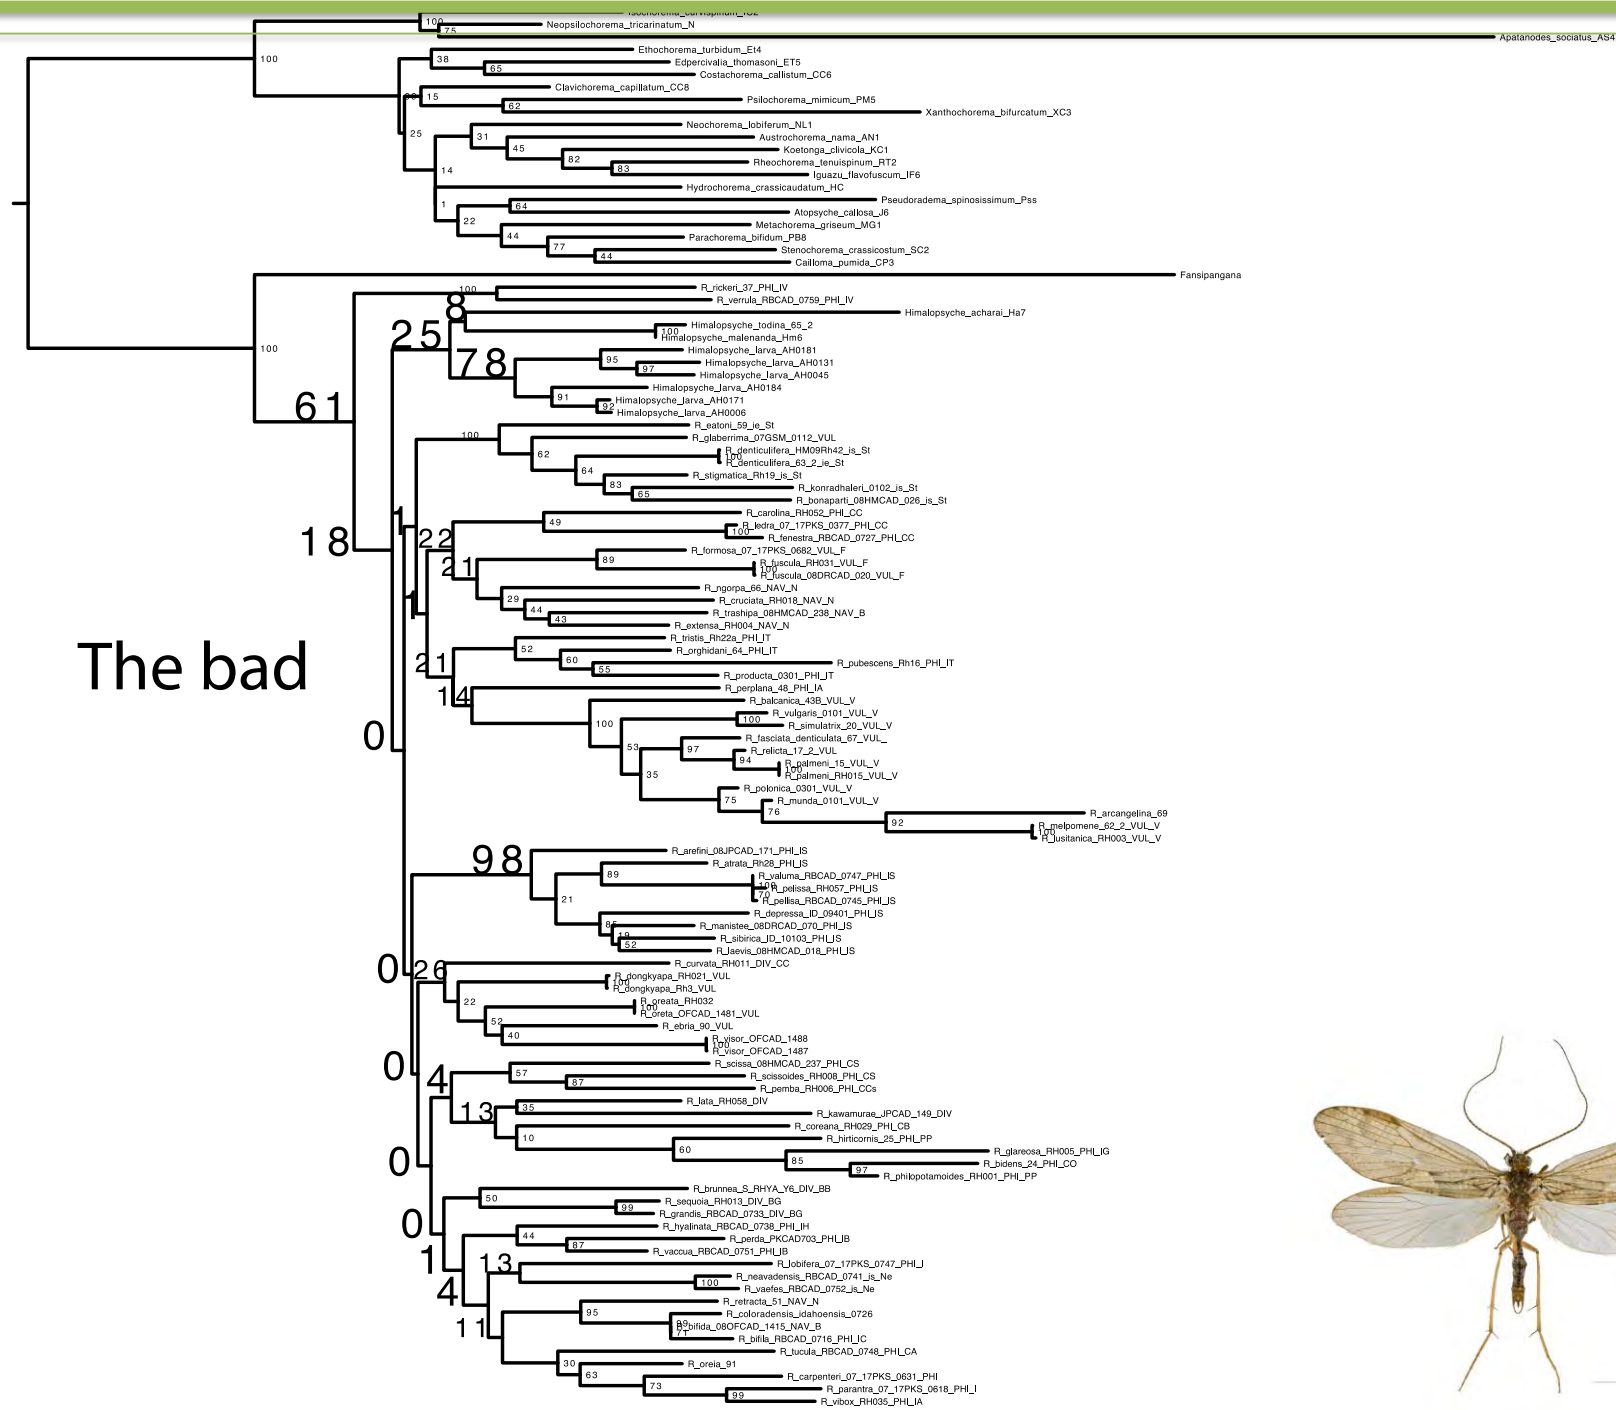

700 + species

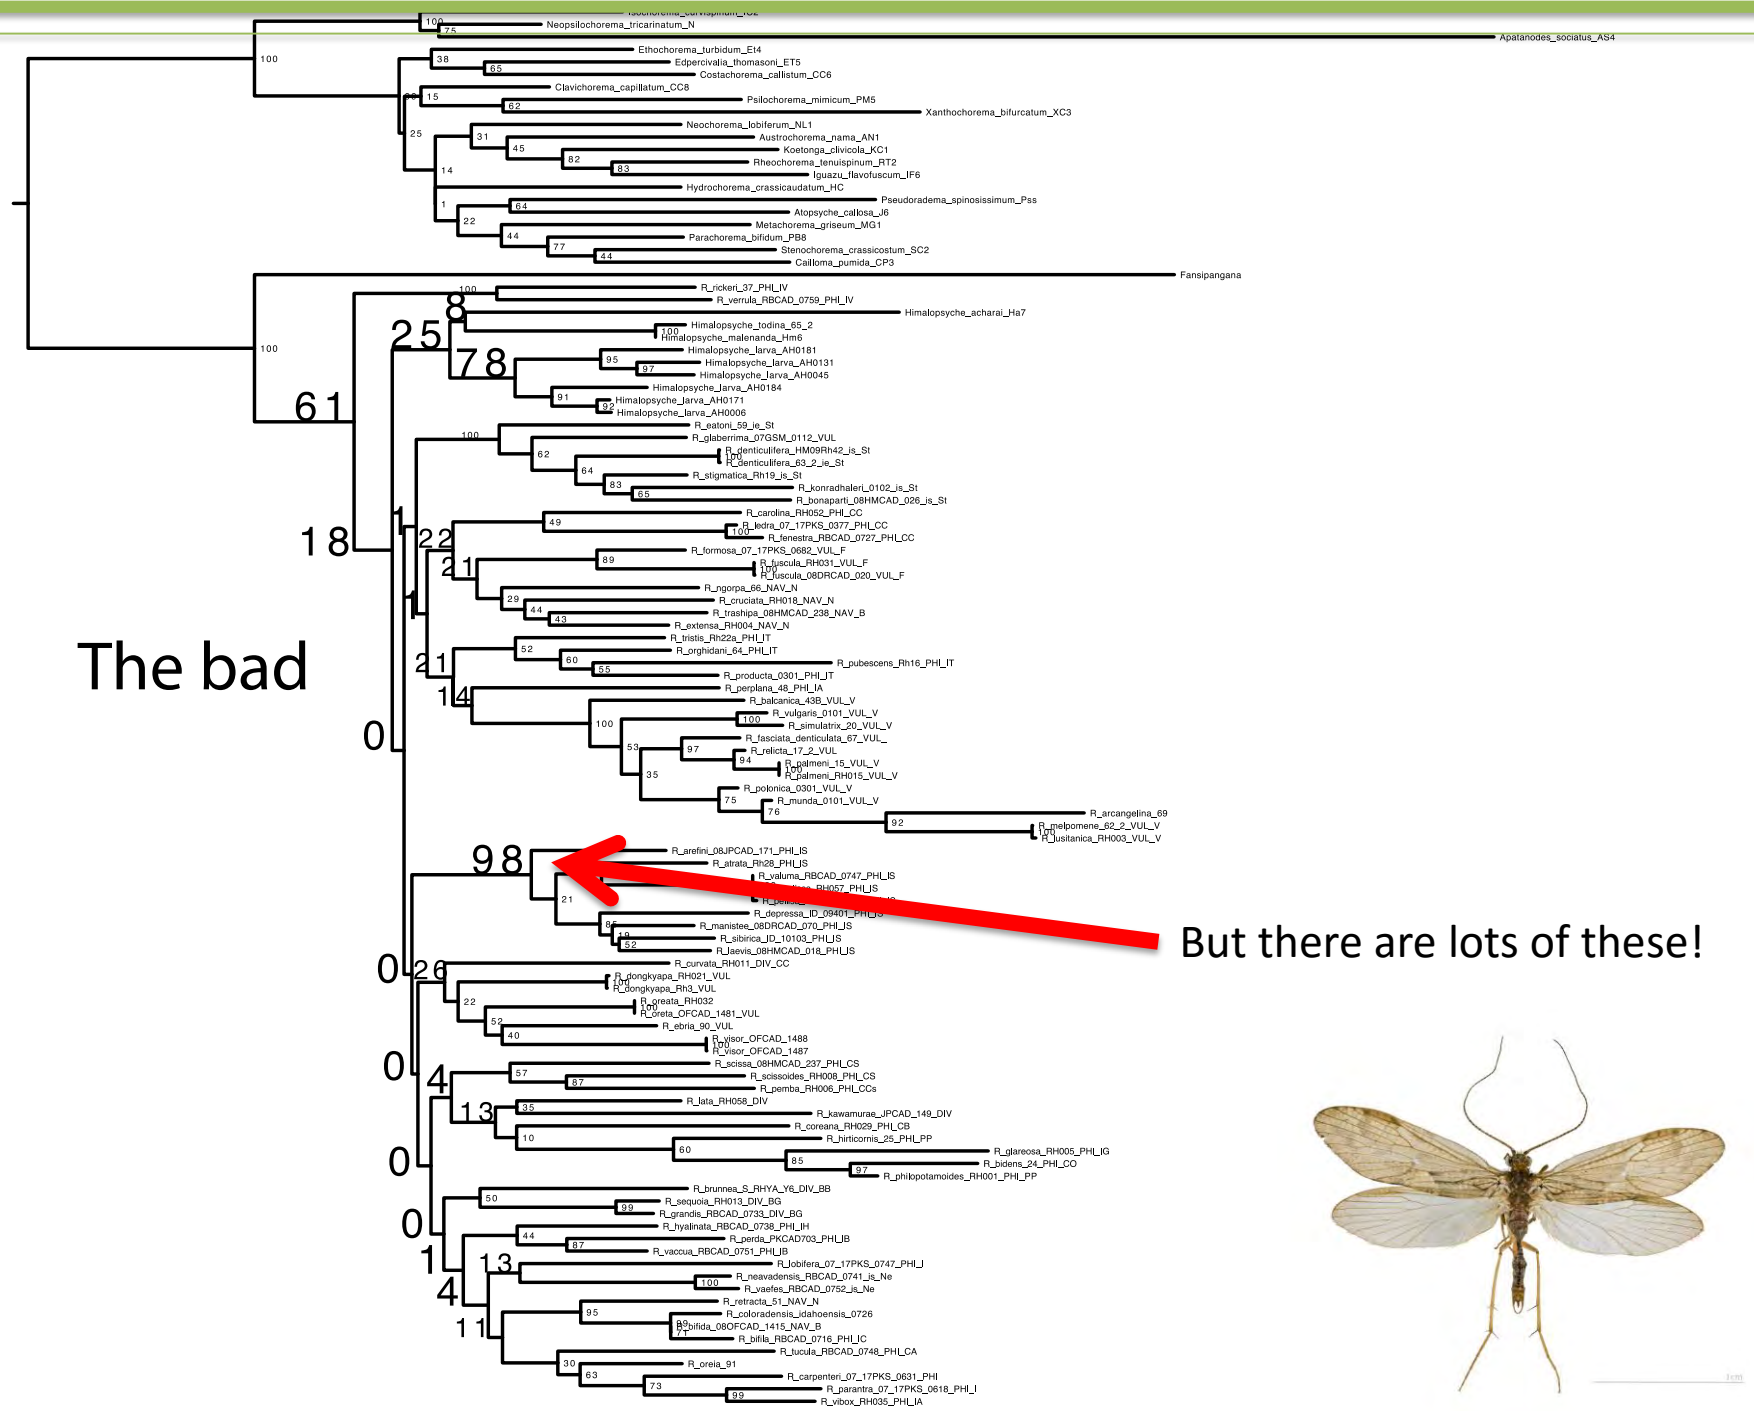

Second only to *Chimarra*

Abstract.—The field of phylogenetics is on the cusp of a major revolution, enabled by new methods of data collection that leverage both genomic resources and recent advances in DNA sequencing. Previous phylogenetic work has required labor-intensive marker development coupled with single-locus polymerase chain reaction and DNA sequencing on clade-by-clade and locus-by-locus basis. Here, we present a new, cost-efficient, and rapid approach to obtaining data from hundreds of loci for potentially hundreds of individuals for deep and shallow phylogenetic studies. Specifically, we designed probes for target enrichment of >500 loci in highly conserved anchor regions of vertebrate genomes (flanked by less conserved regions) from five model species and tested enrichment efficiency in nonmodel species up to 508 million years divergent from the nearest model. We found that hybrid enrichment using conserved probes (anchored enrichment) can recover a large number of unlinked loci that are useful at a diversity of phylogenetic timescales. This new approach has the potential not only to expedite resolution of deep-scale portions of the Tree of Life but also to greatly accelerate resolution of the large number of shallow clades that remain unresolved. The combination of low cost (~1% of the cost of traditional Sanger sequencing and ~3.5% of the cost of high-throughput amplicon sequencing for projects on the scale of 500 loci × 100 individuals) and rapid data collection (~2 weeks of laboratory time) are expected to make this approach tractable even for researchers working on systems with limited or nonexistent genomic resources. [Anchor regions, anchored enrichment, anchored phylogenomics, highly conserved regions, hybrid enrichment, phylogenetics, phylogeography, sequence capture, ultraconserved elements.]

Probes are tiled across entire exons

***Imagine you target 900 exons this way.
Sequence them all in one run...***

My beloved freezer
(good ol' #5; we've been through
a lot together)

It took 20 years, and 200 person years
to collect this...

It is **useless** for transcriptome work

Perfect for exome capture and barcoding!

Rhyacophilidae

Limnephiloidea

Leptoceroidea

Sericostomatoidea

Step 1: Generate a phylogeny among families from transcriptomes (3500 genes)

Step 2: Use transcriptomes to design probes to add compatible targeted enrichment techniques (900 genes). You now have a genus level phylogeny with big data.

Take one family as an example: **Phryganeidae**

We have 900 genes for all but one of the genera

Step 3: look at one genus; *Agrypnia* for example

17 of 19 species

Note: Only 5 taxa are “barcode only” and these need only stick where they go in an otherwise constrained tree

Phryganeidae Agrypnia

17 of 19 species

Now apply this same
technique to the
other 549
genera

The End
